(54) Title: HYDROPHILIC COMPOSITIONS WITH INCREASED THERMAL AND SOLVENT RESISTANCE (57) Abstract A fluid filtration material made of a porous substrate, e.g. a membrane or a fabric that is coated with a fluorinated copolymer that contains recurring vinyl alcohol units to impart hydrophilicity. The material is cross-linked with multifunctional epoxides to maintain hydrophilicity on exposure to heat or solvent.

cross-linking occurs, there is no net loss of hydroxyl functionality. The crosslinking will have a restrictive effect on C-OH bond rotation and also will prevent the copolymer from being solubilized by any solvent. The hydrophilicity is maintained by crosslinking the -OH moieties with a multifunctional epoxide to lock the molecules into a rigid structure, and thus prevent rotation.

Thus, in this invention a hydrophilic composition is provided comprising a substrate, preferably having continuous pores through it, in which at least a portion of the substrate is coated with a copolymer of a fluorinated monomer and vinyl alcohol, wherein the vinyl alcohol units are crosslinked by reaction with a multifunctional epoxide. Preferably the substrate is a microporous fluorocarbon membrane.

DESCRIPTION OF THE INVENTION

The substrate is preferably permeable and can be any material that allows fluids, liquid or gas, to pass through. It is a material that contains continuous passages extending through the thickness of the material, and openings on both sides. These passages can be considered as interstices or pores. Preferably the material is flexible and is in the form of a fabric, sheet, film, tube, mesh, fiber, plug, or the like. Suitable fabrics include nonwovens, wovens, knits, scrims, or the like. The material can also be a porous synthetic or natural polymeric film or membrane, where the pores form the interstices or passageways.

Representative polymers useful in the material include polyamide, polyurethane, polyester, polycarbonate, polyacrylic, polyolefins such as polyethylene and polypropylene, or fluorinated polymers such as polyvinylidene fluoride or polytetrafluoroethylene, polyvinyl chloride and the like. The material will generally be from about 1 to about 200 micrometers thick. In order to promote adherence of the coating to the substrate, the coating should have groups or moieties that have an affinity for the substrate. In other words, if the substrate contains fluorocarbon groups, then a coating material that contains fluorocarbon groups will be more

likely to adhere and be an effective coating. Preferably, the substrate is a flexible porous material such as expanded porous polytetrafluoroethylene (ePTFE) sheet made as described in U.S. Patent 3,953,566 by stretching PTFE resin. The resulting product
5 has a microstructure of nodes interconnected with fibrils. The PTFE resin is stretched so that the micropores or voids that form allow for good gas or air flow while providing liquid water resistance. These porous PTFE sheets, which can be referred to as membranes or fibers preferably have a Gurley number of between 0.1
10 second and 80 seconds, depending on pore size and pore volume.

When the material is polytetrafluoroethylene it will have a porosity volume ranging usually from 15% to 95%, preferably from 50% to 95%.

The copolymers used to coat the substrate can be made by first
15 copolymerizing a fluorine-containing ethylenically unsaturated monomer and a non-fluorinated vinyl acetate.

The fluorine-containing ethylenically unsaturated monomer will be a vinyl monomer such as, for example, tetrafluoroethylene, vinyl fluoride, vinylidene fluoride, monochloro-trifluoroethylene,
20 dichlorodifluoroethylene, hexafluoropropylene, perfluoropropylvinyl ether, and the like. Preferably, the fluorine-containing vinyl monomer can be described as $\text{XCY}=\text{CFZ}$ wherein Z can be fluorine or hydrogen and X and Y can each be selected from hydrogen, fluorine, chlorine, or $-\text{CF}_3$.

25 Once the vinyl acetate-containing copolymer is prepared, the acetate groups are saponified to hydroxyl groups. In this case, not all of the acetate groups contained in the copolymer need be replaced by hydroxyl groups. The conversion of acetate groups into hydroxyl groups need only be carried out to the extent needed to
30 provide the copolymer with hydrophilic properties.

The fluorine content of the fluorine-containing hydrophilic copolymer to be used as the coating in the present invention may range usually from 2% to 40%, preferably from 10% to 40%, and most preferably 20% - 30% on a weight basis. If the fluorine content of
35 the fluorine-containing hydrophilic copolymer becomes too high, the hydrophilic properties of the polymer may be lessened.

The copolymer is fixed with respect to rotation by crosslinking it with a multifunctional epoxide. Representative

epoxides include

ethylene glycol diglycidyl ether, i.e.,

5

1,4-butane diol diglycidyl ether, i.e.,

10

1, 2, 7, 8-diepoxyoctane (a mutagen); 1, 2, 4, 5, 9, 10-triepoxydecane, or the like.

These epoxides are believed to react with the -OH of the TFE/VOH copolymer with no net loss of -OH functions, since the epoxide rings open to form -OH groups in the cross-linking moiety.

15

The coated compositions of the invention may be prepared by first dissolving the copolymer in a solvent containing the epoxides. The solution and a crosslinking catalyst is then applied to the substrate by immersion or spraying or transfer coating. The coated product is then dried and cured in an oven, for example at about 80°C, or can be cured during air-drying.

20

Suitable solvents are those which will dissolve the copolymer, e.g. alcohols, which flash off prior to the curing reaction.

In the following examples, the copolymer employed was a copolymer of tetrafluoroethylene and vinyl alcohol of approximately 25% (by weight) alcohol functionality.

25

Example 1

Example Of Cross-linking Reaction

To 200 ml. of a 9% solution of the TFE/VOH in methanol was added 9.4 g of 50% pure ethylene glycol diglycidyl ether (EGDE) (Aldrich Chemical Co., 0.027 equivalents) in methanol. About 50 ml of this clear viscous solution was poured into a petri dish. This served as an uncatalyzed sample. Another 50 ml. of this TFE/VOH + EGDE solution was treated with 8 g of a 10% aqueous solution of KOH, the catalyst for the cross-linking reaction. This solution mix was vigorously stirred and poured into a petri disk. These

30

catalyzed and uncatalyzed samples were left to cure at room temperature. After 53 hrs., it was observed that the uncatalyzed sample was now a thick film, very clear, with a light yellow tint and was very supple. The KOH catalyzed sample was also a film, thick, fairly clear, more stiff than the uncatalyzed sample. These films were further dried in a vacuum oven at 70°C and 30 in. Hg for 2 hours. They became yellowish and much stiffer.

To determine whether cross-linking had occurred, the following was done:

In three separate beakers containing dimethylformamide (DMF), (1) a pure TFE/VOH film was added to one; (2) a sample of the uncatalyzed TFE/VOH + EGDE film was added to another; and (3) a sample of the KOH catalyzed TFE/VOH + EGDE film was added to the third. Within 15 minutes it was observed that the plain TFE/VOH film had dissolved in the DMF while the other two samples had swollen a little. After overnight immersion, there was still no change, the TFE-VOH treated with the EGDE had still not dissolved.

The above results indicated that reaction with the EGDE had made the TFE/VOH insoluble, thus indicating that cross-linking had occurred.

Example 2

A microporous PTFE membrane that has a nominal pore size of 0.1 micron was treated with a 1% TFE/VOH solution in methanol/ethanol (4:1) membrane (sample 2.1). A sample of this membrane was immersed for 5 minutes in an aqueous solution of 2% ethylene glycol diglycidyl ether/0.2% potassium hydroxide (sample 2.2). This sample was stretched on a hoop and allowed to dry at room temperature overnight.

The same procedure was followed for a 0.45 micron pore size microporous PTFE membrane (TFE/VOH only treated material: sample 2.3; a portion of sample 2.3 was immersed for 5 minutes in aqueous 2% ethylene glycol diglycidyl ether/0.2% potassium hydroxide, stretched on a hoop and dried at room temperature overnight (sample 2.4).

A 0.2 micron pore size microporous PTFE laminate was treated

with a 2% TFE/VOH solution in methanol/ethanol (4:1) and dried to yield a water-wettable material (sample 2.5). A portion of this sample was immersed for 5 minutes in a 2% ethylene glycol diglycidyl ether/0.2% potassium hydroxide aqueous solution, stretched on a hoop and allowed to dry at room temperature overnight (sample 2.6).

All of the above samples were immediately and completely water-wettable.

Testing of Durability of Water-wettability to Steam Heat

Portions of the above six samples were fixed on metal hoops and subjected to autoclaving at 120°C for 90 minutes. Immediately after this period of exposure to high temperature steam, the samples were contacted with water and their water-wettability was observed:

<u>Sample Number</u>	<u>Water-wettability After Autoclaving</u>
2.1	No longer wettable
2.2	Completely wettable; a few seconds delay
2.3	No longer wettable
2.4	Completely wettable; a few seconds delay
2.5	No longer wettable
2.6	Completely wettable; a few seconds delay

These results indicate that crosslinking TFE/VOH with EGDE on a membrane produces a membrane which can maintain water-wettability even after steam sterilization.

Example 3

A treatment solution of 1% TFE/VOH, 1% butanediol diglycidyl ether, 0.5% potassium hydroxide in methanol/ethanol (4:1) was prepared. In this solution, the following samples were immersed:

A microporous PTFE laminate of 0.45 micron nominal pore size was immersed for 1 minute. It was dried in a vacuum oven at 85°C, 30 inches mercury pressure, for 2.5 minutes. (Sample 3.1).

A microporous PTFE laminate of 0.45 micron nominal pore size was immersed for 5 minutes. It was dried in a vacuum oven at 85°C, 30 inches mercury pressure, for 2.5 minutes. (Sample 3.2).

5 A microporous PTFE laminate of 0.1 micron nominal pore size was immersed for 1 minute. It was dried in a vacuum oven at 70-80°C, 30 inches mercury pressure, for 12 minutes. (Sample 3.3).

10 A microporous PTFE laminate of 0.1 micron nominal pore size was immersed in above solution for 5 minutes. It was dried in a vacuum oven at 70-80°C, 30 inches mercury pressure, for 12 minutes. (Sample 3.4).

All of the above samples were completely and immediately water-wettable.

15 Testing of Durability of Water-wettability to Steam Heat

20 The above four samples were fixed on hoops and subjected to steam sterilization conditions: 120°C for 90 minutes. All samples were completely water-wettable. The samples that had been immersed in the treatment solution for only 1 minute appeared to wet out faster than those immersed for 5 minutes.

Example 4

Four samples were prepared as follows:

25 Sample 4.1: On a tenter frame, a microporous PTFE membrane of 0.1 micron nominal pore size was treated with a 1% solution of TFE/VOH (in methanol/ethanol 4:1), followed by dipping in ethanol/water (2:1), followed by dipping in water. This sample was dried in an oven at 80°C for 6 minutes and further dried at room temperature

overnight. The dry, treated membrane was immediately and completely wettable in water.

5 Sample 4.2: Treatment solution was 1% TFE/VOH, 1.45% butanediol diglycidyl ether, 0.09% potassium hydroxide in methanol/ethanol (4:1). A microporous PTFE membrane of 0.1 micron nominal pore size was fixed on a tenter frame and onto this was dripped the above solution while the membrane was moved on the tenter frame at a line speed of 1.5 feet per minute. The length of the tenter frame was 20 feet. By the time that the wetted membrane had travelled
10 approximately 6 feet, much of the solvent had evaporated. The treated membrane was allowed to dry at room temperature. Then the membrane was subjected to the same treatment on the previously untreated side. Drying was again at room temperature. This treated membrane was now completely and immediately water-wettable.

15 Sample 4.3: Treatment solution was 1% TFE/VOH, 1.45% butanediol diglycidyl ether, 0.09% potassium hydroxide in methanol/ethanol (4:1). A microporous PTFE membrane of 0.1 micron nominal pore size was fixed on a tenter frame and treated in the same manner as in example 4.2 with the exception that it was dried in an oven at
20 100°C with a residence time of 4 minutes. This sample was completely and immediately water-wettable.

Durability Testing of the Water-wettability of Above Samples in Dry Heat

25 From each of the three samples above portions of membrane were cut and fixed on hoops. These were placed in an oven at specific temperatures for 1 hour. After the exposure to dry heat, the membranes were allowed to return to room temperature and were then sprayed with water to determine water-wettability. At each
30 specific temperature, a fresh, previously unheated sample piece was dry heat tested. In all cases, exposure time to heat was 1 hour. The results were as follows:

	<u>Sample Number</u>	<u>Temperature (°C)</u>	<u>Water-wettability After Exposure to Heat</u>
5	4.1	130	Complete and immediate
	4.2	130	Complete and immediate
	4.3	130	Complete and immediate
10	4.1	140	Incomplete; 10-15 min. to wet
	4.2	140	Complete and immediate
	4.3	140	Complete; 3-4 sec. to wet
15	4.2	150	Complete; 0-4 sec. to set
	4.3	150	Complete; 2-5 sec. to wet
20	4.2	160	Complete; 30-45 sec. to wet
	4.3	160	Complete; 4-10 sec. to wet
	4.2	170	Complete but not perfectly transparent; 20-40 sec.
	4.3	170	Complete; 20-40 sec. to wet

Example 5

This Example demonstrates the solvent resistance of crosslinked TFE-VOH copolymers on an expanded porous PTFE (ePTFE) membrane.

Sample 5.1: Treatment solution used was 1% TFE-VOH in methanol/ethanol (4:1). The ePTFE was a microporous PTFE of 0.1 micron nominal pore size. Treatment of the membrane was performed in the same manner as described in Example 4.1. This sample was completely and immediately water-wettable.

Sample 5.2: Treatment solution used was 1% TFE-VOH copolymers/1.45% butanediol diglycidyl ether/0.095 potassium hydroxide in methanol/ethanol (4:1). The membrane was the same microporous PTFE of 0.1 micron nominal pore size described in the above example. Treatment of the membrane was carried out in the same manner as that described for Example 4.1. This sample was completely and immediately water-wettable.

Determination of Solvent Resistance

A pre-weighed portion of samples 5.1 and 5.2 were each separately immersed in 100 ml of N,N-dimethylformamide (DMF) at

room temperature. No agitation was used. While microporous PTFE will not wet with DMF, the above-treated microporous ePTFE wet immediately and completely with DMF. After an immersion duration of 15 hours for each sample, the samples were removed from the DMF, fixed on hoops and allowed to dry at room temperature. Wettability to water of each DMF exposed sample was checked with the following results:

	<u>Sample Number</u>	<u>Wettability and Water</u>
10	5.1	No wetting. Water beads on surface.
	5.2	Approximately 70% of surface area wet within 3-10 minutes.

CLAIM:

1. A hydrophilic, fluid permeable composition comprising a substrate having continuous pores through it in which at least a portion of the interior of the substrate is coated with a copolymer of a fluorinated ethylenically unsaturated monomer and vinyl alcohol, wherein the vinyl alcohol units are cross-linked with a multifunctional epoxide.
2. The composition of Claim 1 in which the substrate is flexible and is in the form of a fabric, sheet, film, tube, mesh or plug.
3. The composition of Claim 2 in which the substrate is comprised of a synthetic polymer or natural polymer.
4. The composition of Claim 1 in which the substrate is comprised of a fluoropolymer.
5. The composition of Claim 4 in which the fluoropolymer is polytetrafluoroethylene.
6. The composition of Claim 1 in which the fluorinated ethylenically unsaturated monomer in the copolymer is tetrafluoroethylene.
7. The composition of Claim 1 wherein the epoxide is a diglycidyl epoxide.
8. The composition of Claim 1 wherein the epoxide is selected from the class consisting of ethylene glycol diglycidyl ether, and 1,4-butane diol diglycidyl ether.
